

Adelson-Velsky & Landis (AVL) Tree

why do we need an AVL Tree?

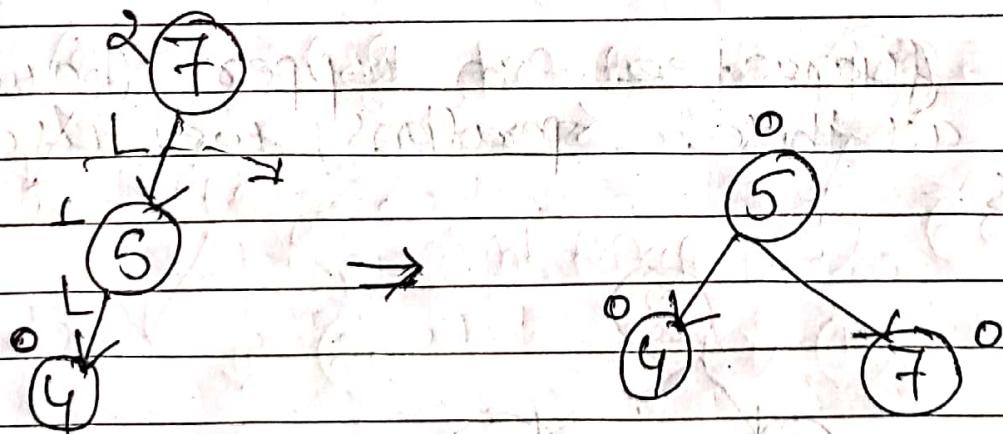

- Almost all the operation in a binary tree of order $O(h)$ where h is the height of the tree.
- If we don't plan our tree properly, this height can get as high as ' n ' where n is the number of nodes in a BST.
- To guarantee an upper bound of $O(\log n)$ for all these operations, we use balanced trees.

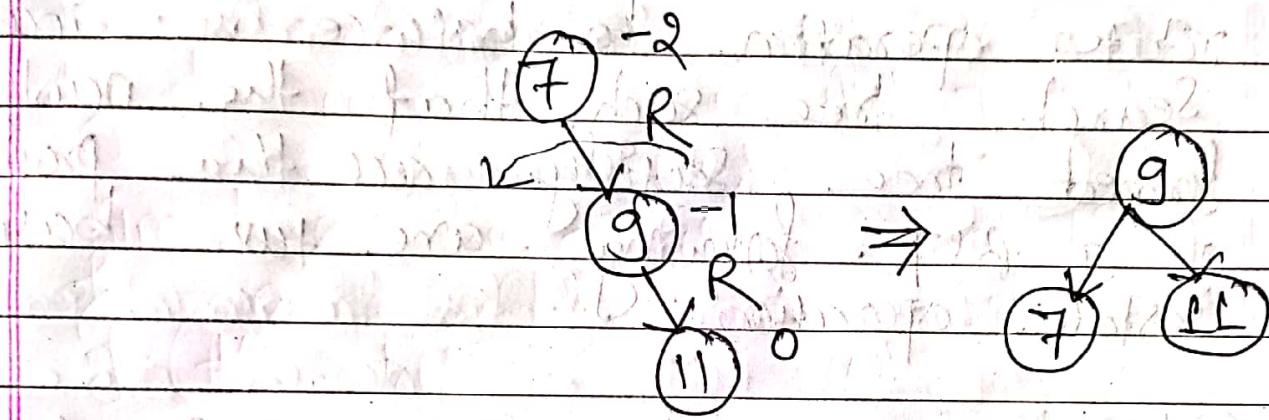

What is an AVL Tree?

- Height Balanced Binary Search trees.
- Balanced factor = height of left subtree - height of right subtree
 $= H(L) - H(R)$
- Balanced factor should be one of $\{-1, 0, 1\}$.

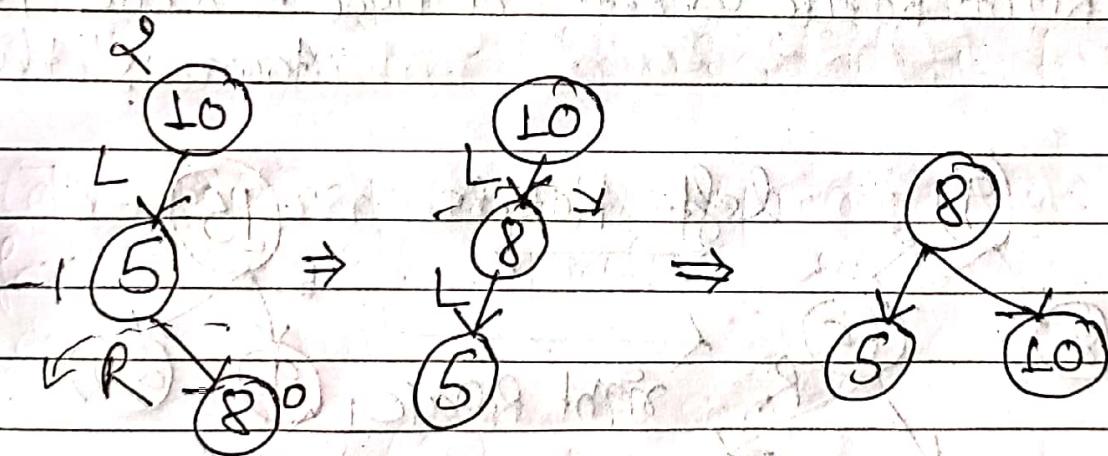

LL Rotation in an AVL

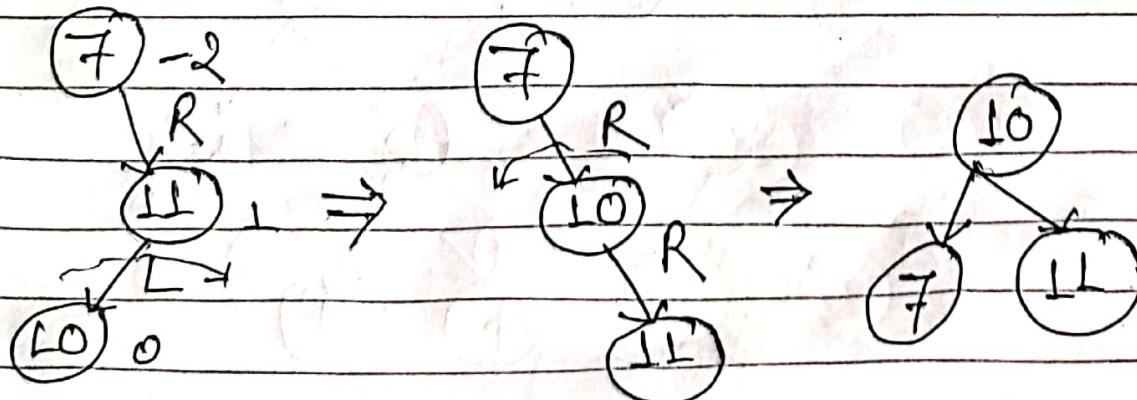

RR Rotation in an AVL

LR Rotation in an AVL

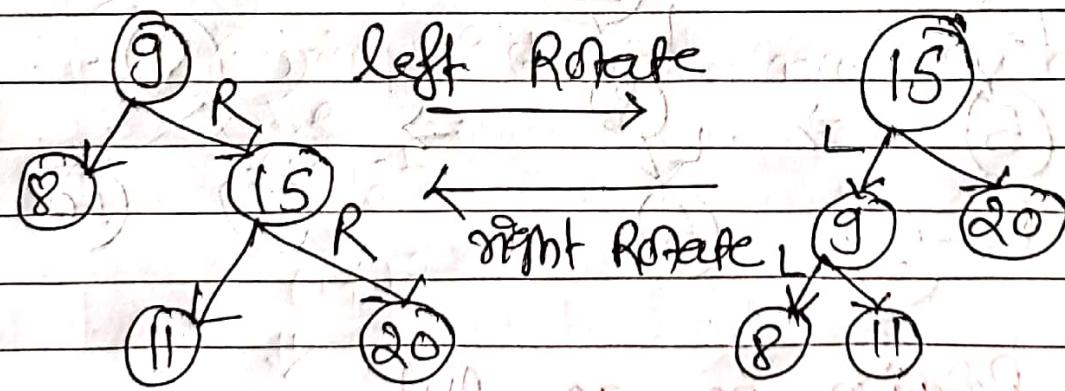

RL Rotation in an AVL

Rotate operations

we can perform rotate operation to balance a binary search tree such that the newly formed tree satisfy all the properties of a BST. following are two basic rotate operations:

- ① Left Rotate w.r.t a node - node is moved towards the left.
- ② Right Rotate w.r.t a node - node is moved towards the right.

Balancing a AVL Tree After Insertion

In order to balance an AVL tree after insertion, we can follow the following rules:

- I. for a left-left insertion \rightarrow Right rotate once w.r.t the first imbalanced node.
- II for a right-right insertion \rightarrow Left rotate once w.r.t first imbalanced node.
- III for a left-right insertion \rightarrow left rotate once and then right rotate once.
- IV for a right-left insertion \rightarrow Right rotate once and then Left rotate once.

Left Left Insertion

AVL Tree

for a left-left insertion \rightarrow
Right rotate once w.r.t
the first imbalanced node.

Right - Left Insertion

7 -2 ← Second Imbalanced node.

0 L 10 -2 ← First Imbalanced node

17 L child of first imbalanced node in path of inserted node.

16 0 new node

7 -2 ← Second Imbalanced node

0 L 10 -2 ← First Imbalanced node

16 R
17 0

7 -1

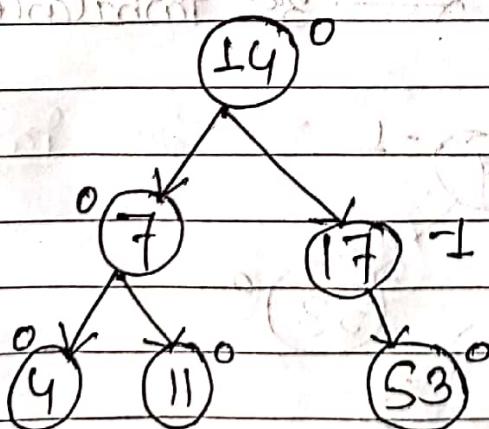

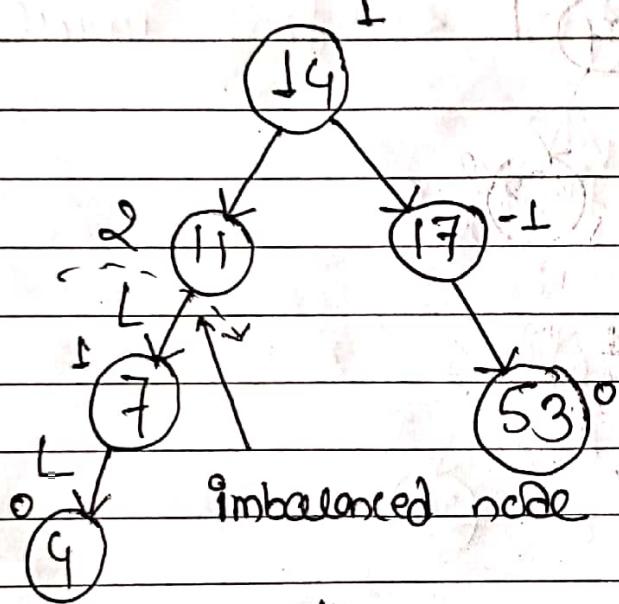

16 0

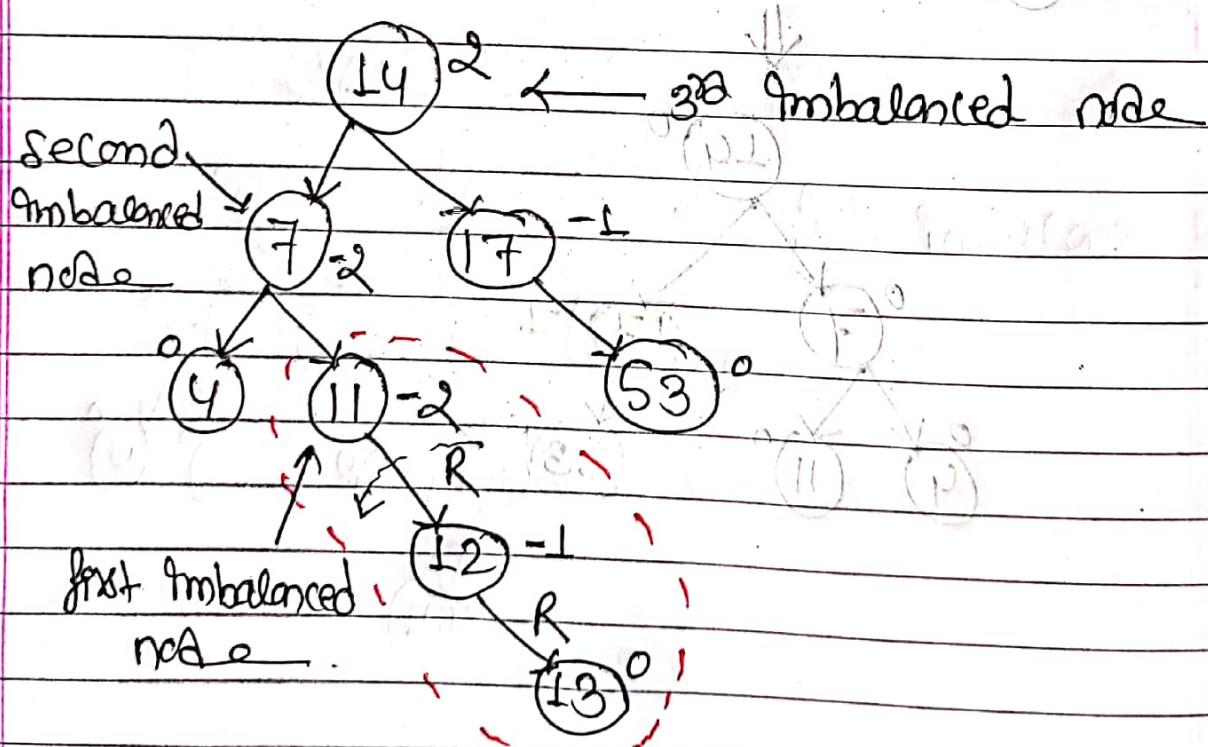

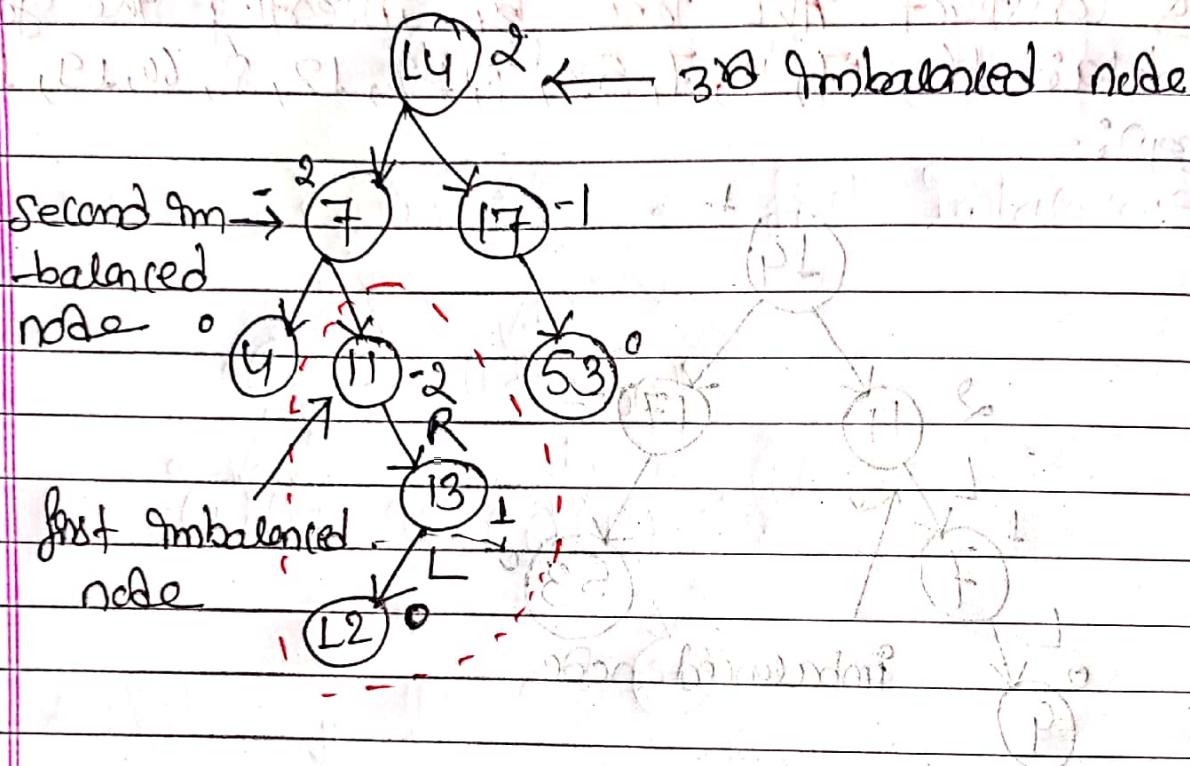

10 0 17 0

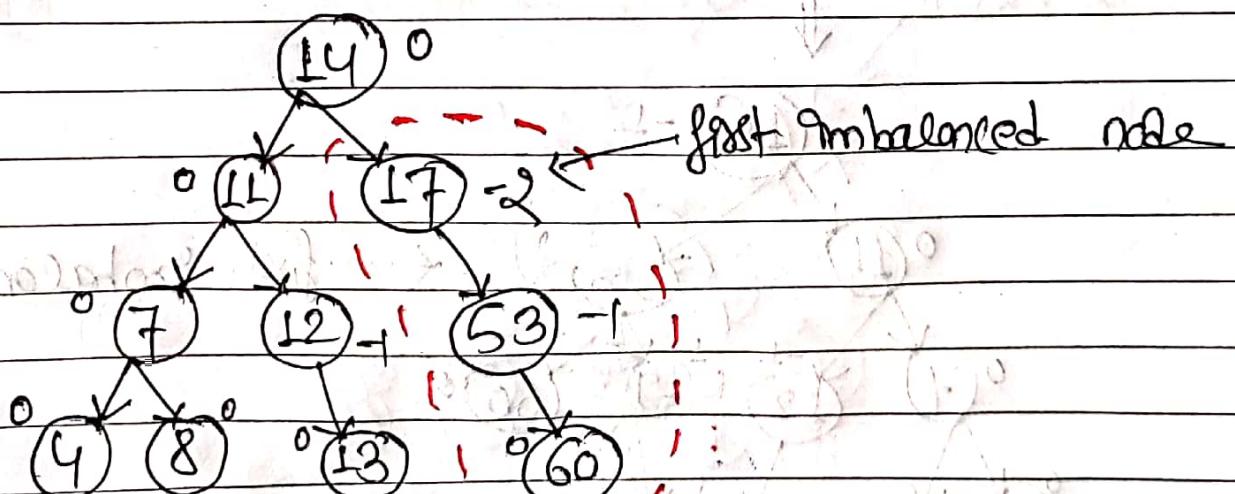

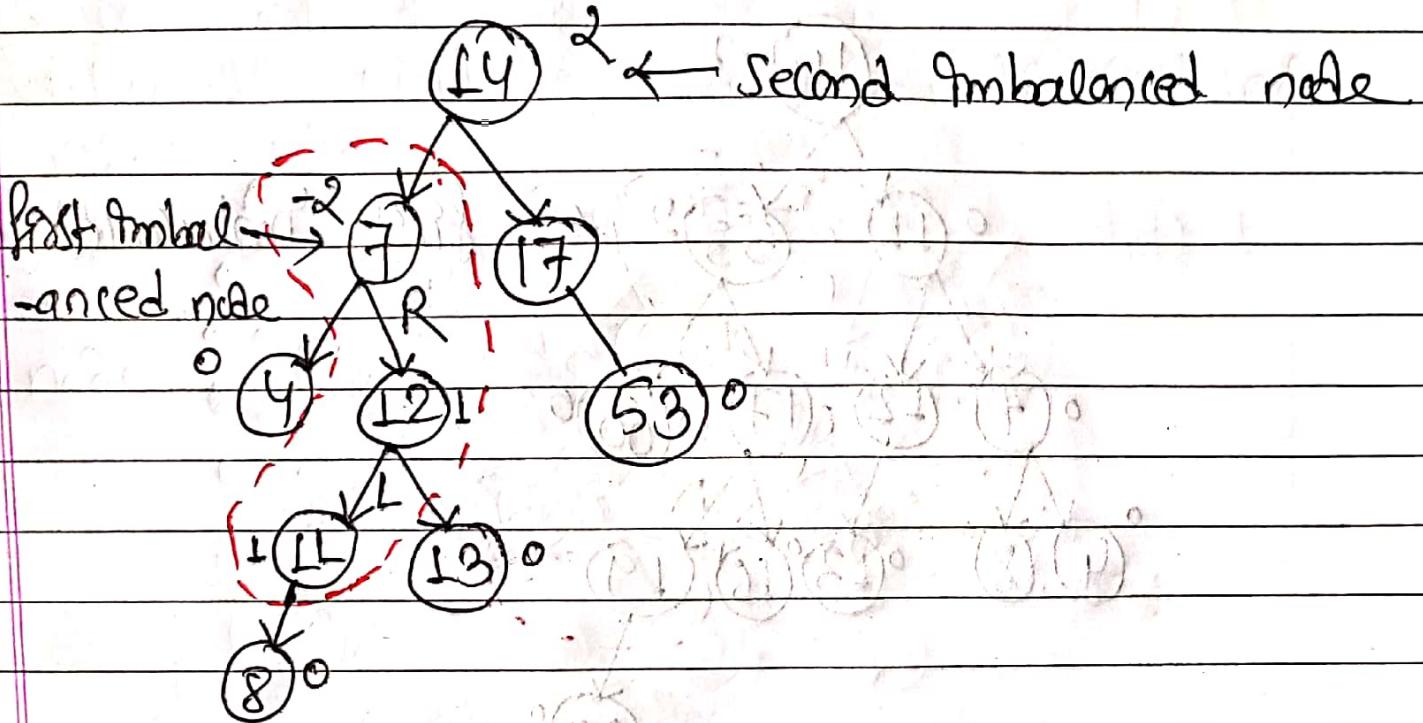

→ AVL Tree

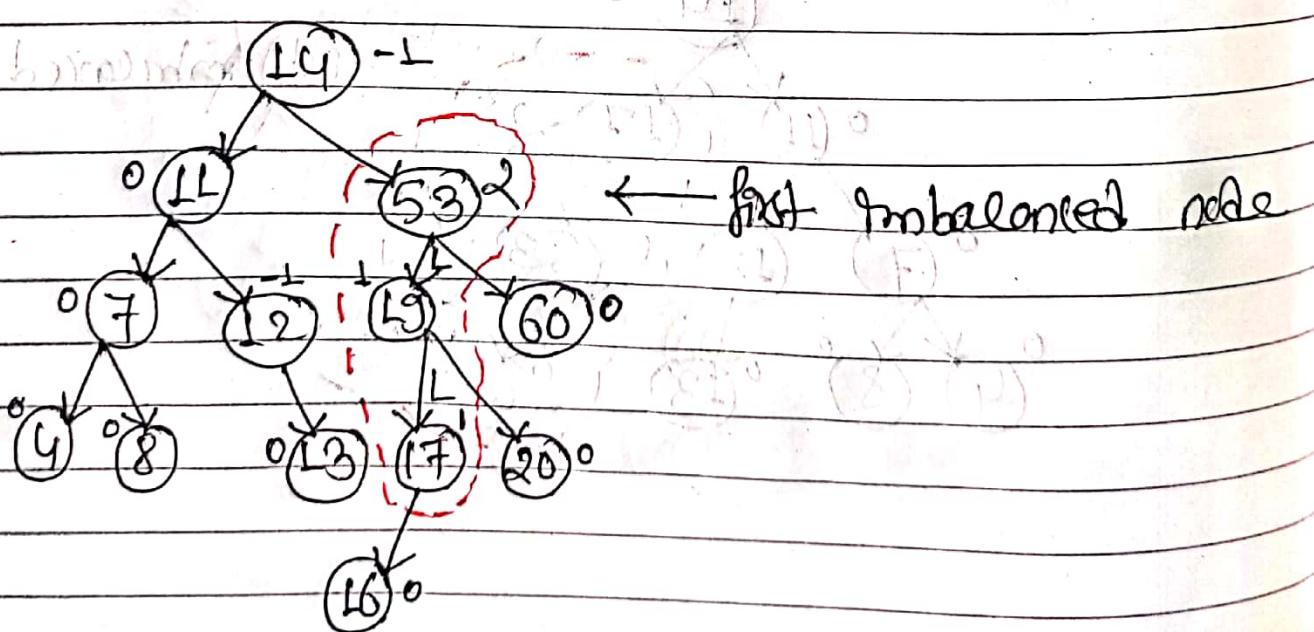

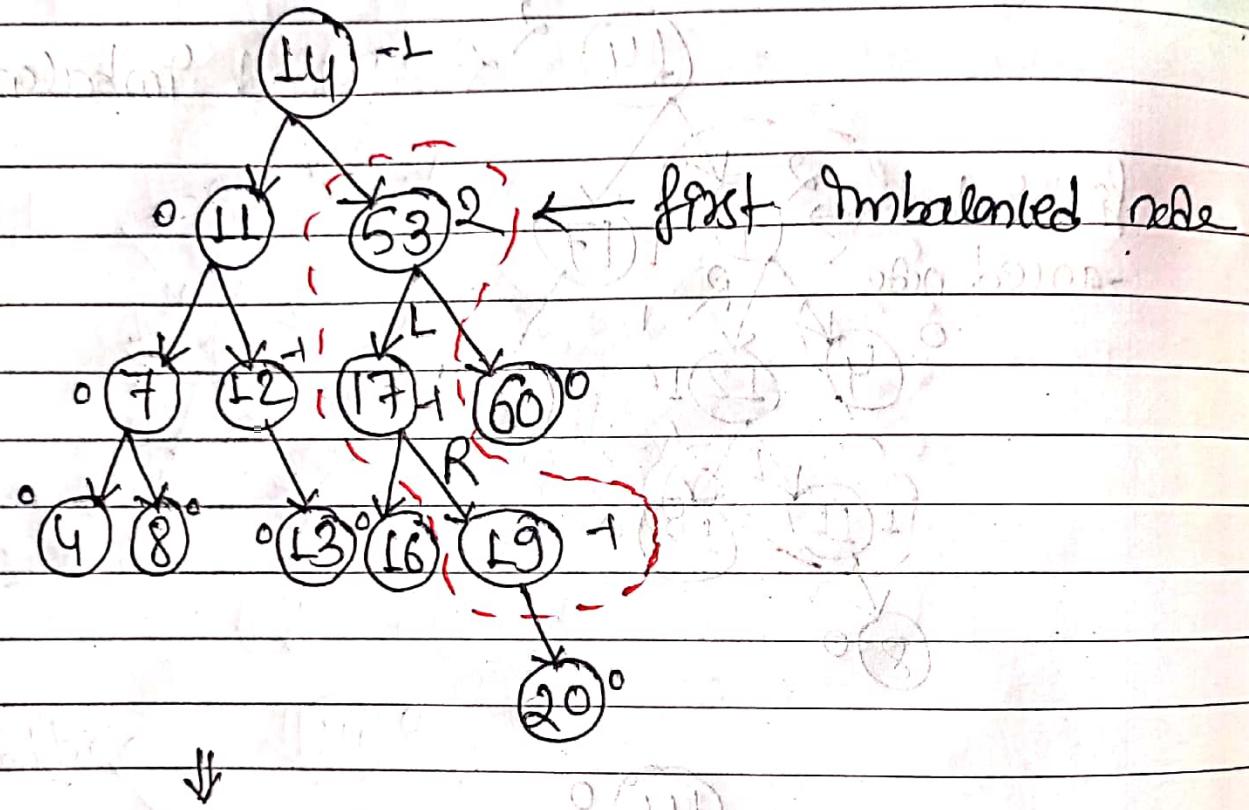

& Construct AVL tree by inserting the following data :- 14, 17, 11, 7, 53, 9, 13, 12, 8, 60, 19, 16, 20.

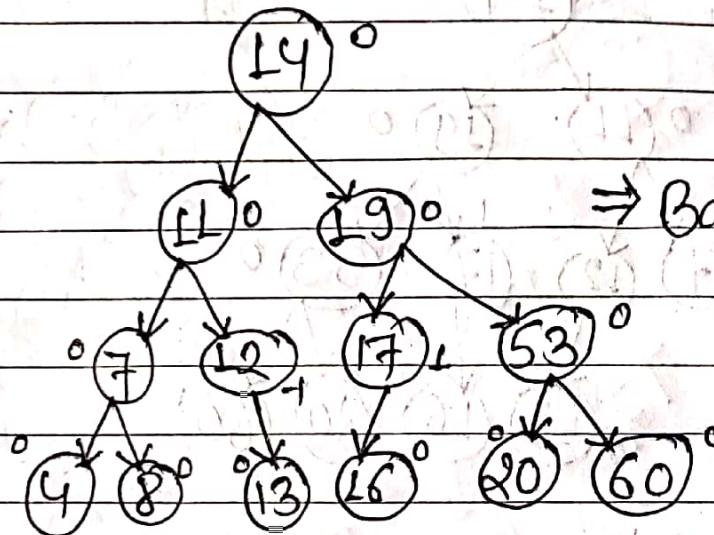

Step :-

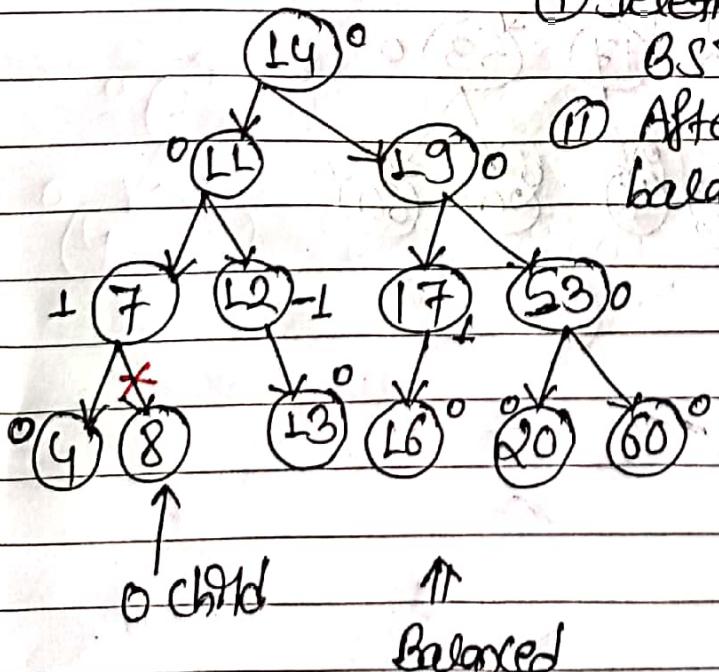

\Rightarrow Balanced AVL Tree

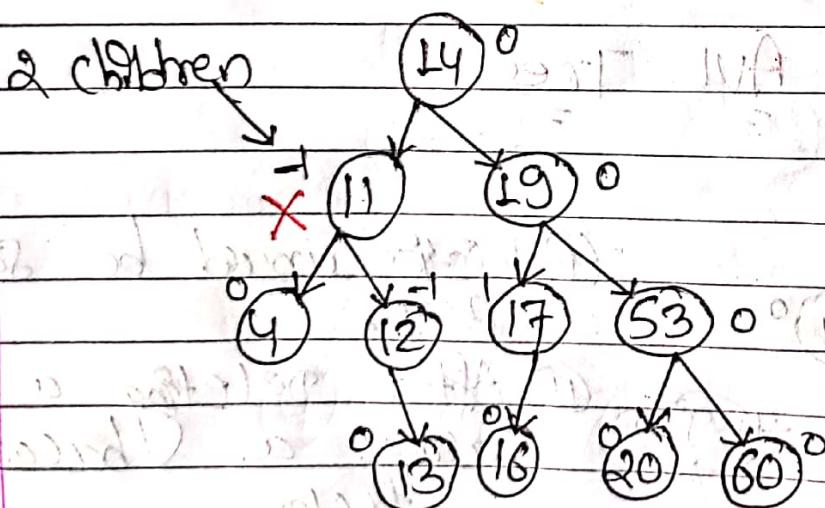

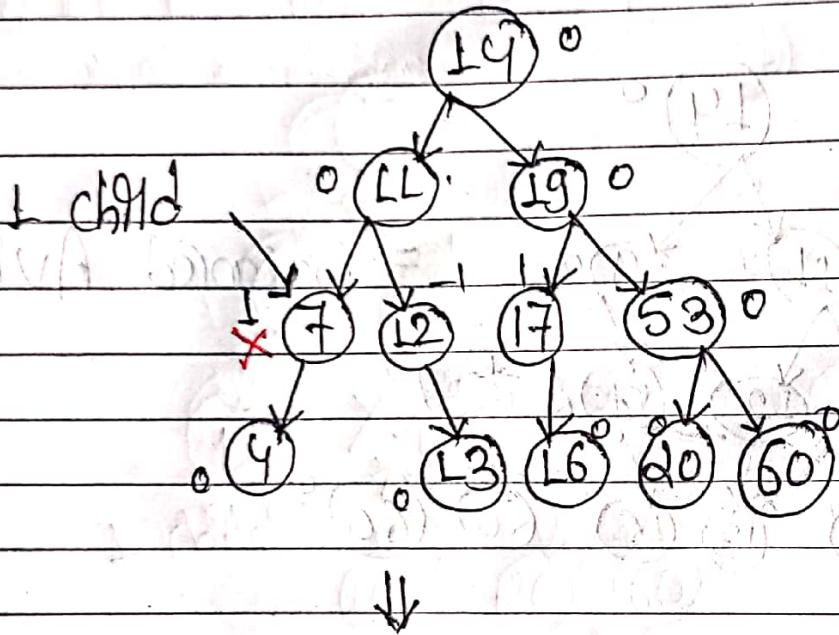

Deletion in AVL Tree

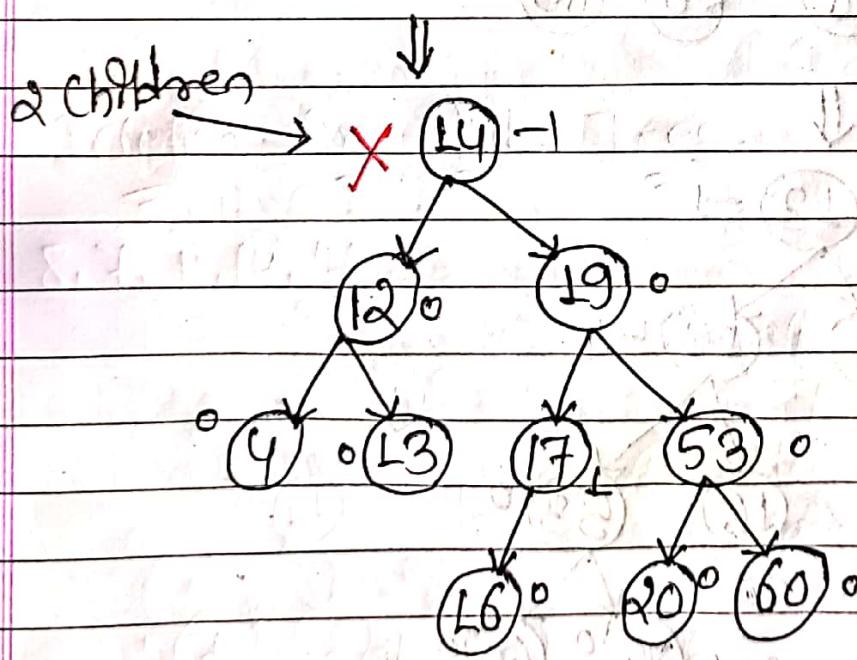

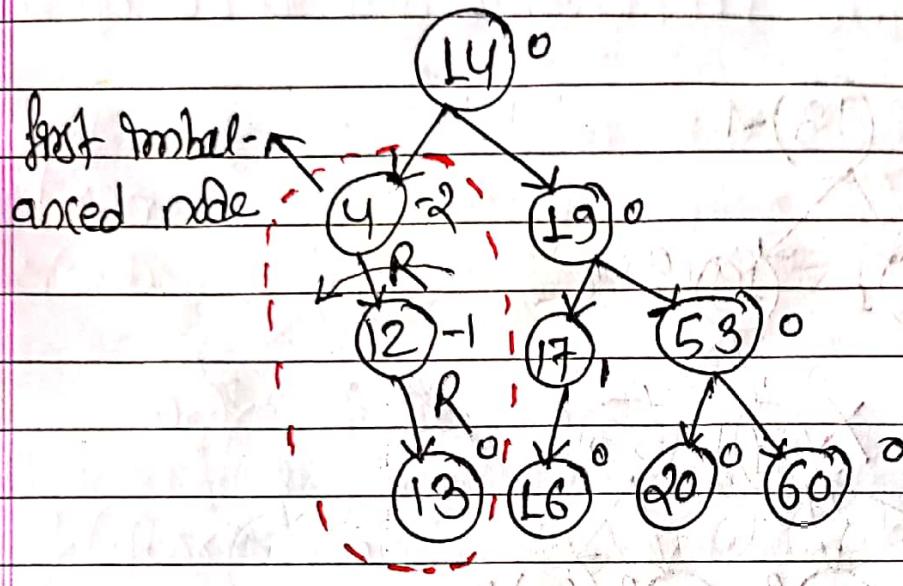

8, 7, 11, 14, 17

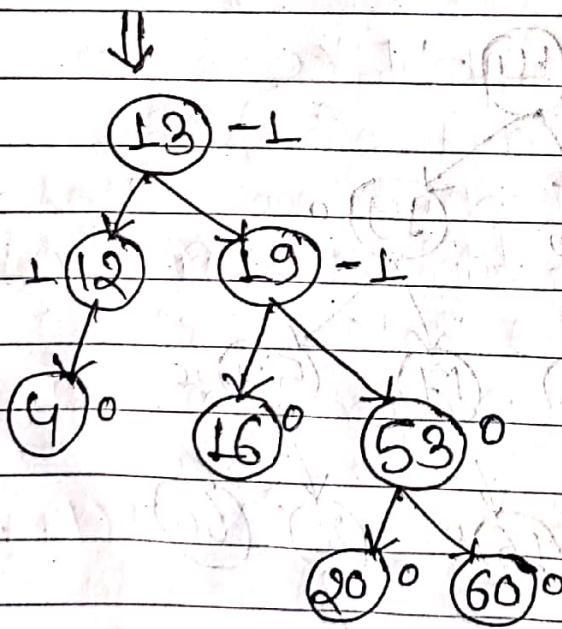

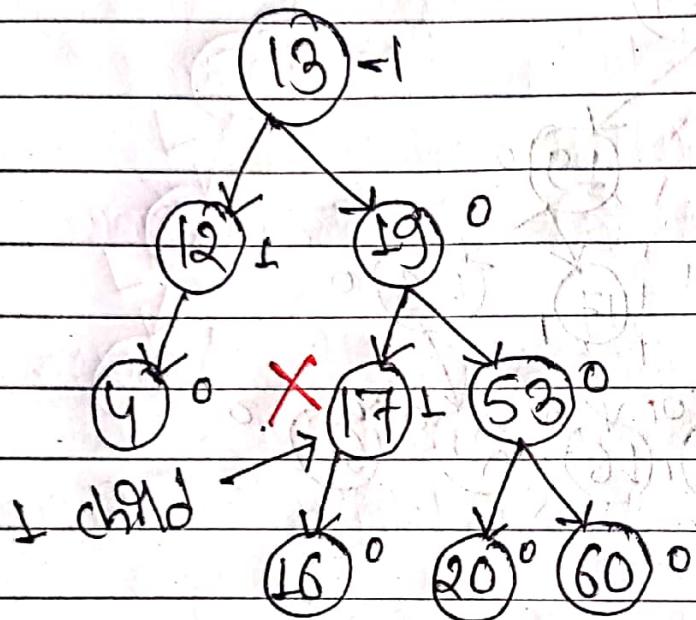

(i) Deletion would be same as BST.

(ii) After deleting a node balance a. If factor.

II To Calculate the Height of a node

```
int Height (node *root) {
    if (root == NULL)
        return 0;
}
```

int left_Height = Height (root → left);

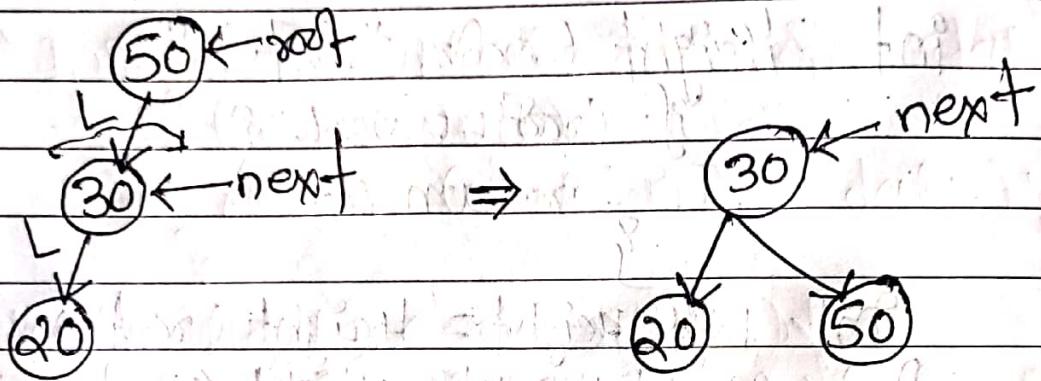

int right_Height = Height (root → right);

return max (left_Height, right_Height) + 1;

II Balance factor of a node {-1, 0, 1}

```
int net_Balance_Factor (node *root) {
    return Height (root → left) - Height (root → right);
```

II LL Rotation (Unbalance due to LL operation)

node * Right-Rotate (node *root) {

 node *next = root → left;

 node *temp = next → right;

 // performing Right Rotation

 next → right = temp;

 root → left = temp;

 return next;

}

LLR Rotation (Unbalance due to RR operation)

```

node *left_Rotate( node *root ) {
    node *next = root->right;
    node *temp = next->left;
}

```

// performing left Rotation

next->left = root;

root->right = temp;

return next;

}

// Insertion in AVL

```

node *Insertion-In-AVL(node *root, int data) {
    if (root == NULL) {
        return CreateNode(data);
    }
    else if (data < root->data) {
        root->left = Insertion-In-AVL(root->left, data);
    }
    else {
        root->right = Insertion-In-AVL(root->right, data);
    }
    int BF;
    BF = Net-Balance-Factor (root);
    // LL Rotation
    if (BF > 1 && data < root->left->data) {
        return Right-Rotate (root);
    }
    // RR Rotation
    else if (BF < -1 && data > root->right->data) {
        return Left-Rotate (root);
    }
    // RL Rotation
    else if (BF < -1 && data < root->right->right->data) {
        root->right = Right-Rotate (root->right);
    }
}

```

return Left-Rotate (root);

Advantages of AVL Trees

- The height of the AVL tree is always balanced the height never grows beyond $\log N$, where N is the total number of nodes in the tree.
- It gives better search time complexity when compared to simple Binary Search trees.
- AVL trees have self-balancing capabilities.
